SOLAR INFLUENCE.

It is Difficult For a Fire to Burn in the Sunlight.

"Did you ever know that fires don't burn as well in sunlight as they do in the shade or at night?" asked my friend, the man much given to hunting and fishing. "Of course they don't seem to because of the greater light from the sun, but I mean as an actual fact they don't. I noticed this thing when on a hunting trip up in Maine first, and how it happened to attract my attention was that the fire went out, totally out, before the sticks were entirely consumed. The wood was dry and resinous, and there was no reason why every particle of it shouldn't have burned. The guide told me he had noticed the same sort of thing innumerable times when fires were burning in the sunlight, and this started me on an investigation which proved in actual practice that open fires not only don't burn so well when the sun's rays are shining on them and fail to throw out as much heat by thermometric tests, but often are actually extinguished by the sun if the rays are bright and strong enough. Coal fires are affected just the same as wood. Strange to say, several scientists to whom I have appealed asserted that the sun's rays could have no effect whatever on a fire. They do, however. I know this beyond all shadow of doubt, and I wonder what the reason is. Other scientists say it's because the heat of the sun adds to the consumption of oxygen of the atmosphere which is necessary to a blaze and also produces carbon, which helps to extinguish the fire."—New York Press.

No Use For Them.

"Come, Willie; get up!" said an indulgent father to his son the other morning. "Remember, the early bird catches the worm."

"What do I care for worms?" replied Willie. "Mother won't let me go fishing."
