Making Money On the Farm

XVI.—Orchard Management

By C. V. GREGORY. "Home Course In Modern Agriculture" Copyright, 1909, by American Press
Association

OR a few years after the young orchard is set out it will do better if it is cultivated. During these first few years, before the trees come into bearing, it is neither necessary nor desirable to let the land lie idle. Some cultivated crop can be grown between the rows of trees, thus utilizing the land and givleaguers, now out barnstorming, that ing the erchard the needed cultivation. Corn is not a very good crop for this purpose, since it grows too rank, shad-Why is it that women are so be- ing the young trees and depriving them can be grown in a young orchard. Squashes and cabbages also fit in well. At least we could get along nicely. It is often convenient to have the vegthe first few years. Small fruit can also be profitably grown as a filler crop. Where bush fruits are used, however, they must be cut out as soon

as the orchard comes into bearing.

FIG. XXXI-PLUMS HANGING THICK. come within three or four feet of the young trees, as they need plenty of

sunlight and moisture. The filler crop should receive frequent and thorough cultivation. soon as the land can be worked in the spring it should be plowed, unless this has been done the fall before. After plowing the disk or spring tooth barrow very effectively breaks up the clods and fines the surface. A final harrowing will complete the process of getting the soil in shape,

Cultivation.

There are two principal objects in cultivating the orchard. In the first place, cultivation, as explained in ar-Archimedes had just announced that ticle No. 2, liberates plant food and so growth. It is a wasteful practice to ready there available by cultivation. The second reason for tiliage is to

conserve moisture and promote deep that day being men exclusively, mean- rooting. The upper layer of a cultivated soil is dry, and in consequence the roots will turn downward to seek a layer in which there is more moisture In order to have every thing about At the same time the upward rise of evaporation. It is very important to make the soil a vast storehouse of moisture for orchard trees, since they must have large quantities if they are apple tree gives off as much as 250 gal lons of water a day through its leaves during the summer months.

Cover Crops.

As the trees come into bearing the can't get well, in order to have time to growth of a cultivated crop between the rows should be discontinued. Some cultivation, however, will still be nec essary if the best results are to be se clover or some legume as a catch crop. This will supply the soil with nitrogen ican countries, with Iowa. This region not always have time to repent at ical condition. Calves, sheep or hogs and humus and keep it in good physmay be turned into the orchard in the fall to eat the clover, or it may be

The trees will be so large by this time that it will be impossible to cul-If you have a robber scheme, don't tivate close to them, nor is this necessary, since the feeding roots are farrows. The space close around the trees may be seeded to blue grass or some other perennial.

As the orchard gets older it may be left in clover for two or three years went to Chicago for a rest, returned at a time. An occasional plowing and reseeding will be necessary to renew the clover and to prevent the orchard from becoming sod bound. If used as a hog pasture the hogs will keep the soll loosened up sufficiently, at the same time adding considerable fertility. In such a case all the treatment that is necessary is an occasional reseeding. If well fed the hogs will do no damage to the apple trees. On the other hand, they will do a great deal of good by eating wormy fruit

and thus destroying the worms. Where it is not convenient to allow hogs or sheep i: the orchard an occasional load of well rotted stable manure will be beneficial. Do not pile!

this around the trees, but scatter it evenly over the ground. Wood ashes are a good substitute for manure, but can seldom be obtained in sufficient amounts to be used to advantage.

If the orchard is properly attended to from the start little pruning will be necessary. It is much better to pinch off a twig occasionally than to cut off a branch as big as your arm a few years later. It takes but a little time to go over the orchard in the spring and clip off such twigs as do not seem to be needed. The object should be to produce an even, spreading, somewhat open head. If it ever does become necessary to remove large branches they should be cut close to the trunk and the wounds painted with white lead. It is better to do this severe pruning in the winter be fore the sap begins to run.

Spraying For Insects.

One of the most effective means of securing large crops of fruit is spraying. Fruit trees of all kinds are sub ject to many injurious insects and diseases, which if left to themselves will materially lessen the yields. There are two kinds of insects-biting and suck ing. The former can be combated by means of poisons sprayed upon the leaves. The sucking insects, of which plant lice are the most common examples, cannot be killed in this way, since they drill into the plant and suck the juices. The most effective remedy for them is some insecticide which will kill by contact, like kerosene emulsion. This is made by dissolving half a pound of soap in a gallon of boiling water, adding two gallons of kerosene and churning the mixture violently until the oil is thoroughly mixed with the soapsuds. This is diluted with nine times as much water before using. It may be applied with a spray pump whenever the lice are troublesome and is a very effective remedy.

The biting insects are by far the most troublesome in the orchard. Of these the codling moth probably does the most damage. It is the larvae hatched from the eggs of the codling moth that cause wormy apples. The tent caterpillar and canker worm at tack the leaves, sometimes stripping the tree bare. There is no better remedy for these insects than paris green dissolved in water at the rate of one pound to 100 gallons. Three pounds of freshly slaked lime should be added to prevent injury to the foliage. Paris green can also be used for the plum curculio and for the other insects which attack the plum and cherry. The foliage of these trees is more tender than that of the apple, however, and for that reason some less severe insecticide, such as arsenate of lead dissolved at the rate of three pounds to fifty gallons of water, is better.

Spraying For Fungous Diseases.

The most troublesome fungous diseases are apple scab, plum, pear and cherry leaf spot and peach leaf curl. The most efficient fungicide is bor deaux mixture. This is made by dissolving four pounds of copper sulphate and four pounds of lime in fifty gal lons of water. The object of a fungicide is not to cure diseases, but to pre vent them. These fungous diseases spread by means of spores, which are carried from leaf to leaf by the wind When they alight on a leaf, especially if the surface is a little moist, they grow and produce another center of disease. If the leaf is covered with a thin coating of the copper sulphate mixture the spores are killed before they start to grow. Since fungicides are preventives rather than cures it is important that they be applied early In order to save time paris green may be added to the bordeaux mixture at the rate of four ounces to fifty gallons or arsenate of lead at the rate of two pounds to fifty gallons and one spray ing made effective for both insects and

If you have many fruit trees it will pay to send to the experiment station for a spraying calendar, which will

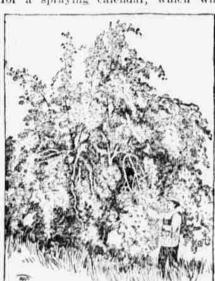

FIG. XXXII-HARVESTING APPLE CROP. give full directions concerning time and manner of spraying. For apples the first spraying should be given about the time the first leaves burst the buds, the second just before the blossoms open and the third just before they fall. If necessary, a fourth spraying may be given from ten to twenty days after the third. In late July or early August another spraying should be given for the second brood of the codling moth. The two most important sprayings are just before the blossoms open and just after they

Boxes are better than barrels for marketing high class fruit, as the fruit can be presented more attractively in this way. There is an advantage in a small package, too, as people will often buy a box of apples when they would never think of buying a barrel.
